Abstract

This paper considers a problem of fault detection, isolation and identification of its values in mechatronic systems described by nonlinear dynamic models. To solve this problem logic-dynamic approach and special feedback by residual signal is suggested. This approach consists of three main steps: replacing the initial nonlinear system by certain linear logic-dynamic system, obtaining the bank of linear logic-dynamic observers, and transforming these observes into the nonlinear ones. Logic-dynamic approach allows detecting and isolating faults in nonlinear dynamic systems by using the linear methods for diagnosis in nonlinear mechatronic systems. Feedback of special form introduced in the observers after the detection and isolation of faults. It is allows to determine the value of faults even in nonlinear systems with incomplete observability. The results of mathematical simulation fully confirm the efficiency and high performance of the proposed method.

Keywords: mechatronic systems; nonlinear models; fault detection; isolation; identification; observers

1. Introduction

One of the possibilities to improve the efficiency of operation of technical systems for critical applications it is operative detection and localization of faults that may occur in elements and subsystems in the process of operation. Timely detection, localization and identification of the values of these faults allow the use of fault-tolerant control methods for the formation of specific control signals that allow to keep the most important characteristics of the system in the presence of faults in it (possibly with a deterioration of the secondary characteristics).

Methods of technical diagnostics are commonly used for the detection and localization of faults. Some of the most widely used methods use the concept of analytical redundancy. This concept presupposes the existence of two or more ways of determining variables of the system. In this case, the diagnosis includes the steps of forming the residual and decision-making. The residual is the result of a mismatch between the behavior of a real diagnosed system and the behavior of its mathematical model (diagnostic observer).

Several methods for synthesis of diagnostic observers for nonlinear dynamical systems are known, including those based on the differential geometric approach [4], the algebra of functions [5, 6], logic-dynamic approach [7, 8, 10] and others [9, 11, 12, 13]. The first two allow obtaining the optimal solution with a minimum dimension of observer, however, have a rather complicated process of finding a solution, because of complex analytical calculations. Logic-dynamic approach does not guarantee a minimum dimension, but the process of finding a solution on its basis is quite simple because of using of linear methods. The task of identifying the values of the faults on the basis of logic-dynamic approach has been solved in [2] and [3], by introducing into the diagnostic observers the signal of feedback by the residual. However, this approach is valid only for the case when the state vector of the diagnosing object fully observable and diagnostic observers has the first order.

In this paper a special feedback by the signal of residual is introduced in the diagnostic observers obtained with the logic-dynamic approach to solve the problem of identification of values of faults. It is allow getting an accurate estimate of the faults occurring in multidimensional nonlinear systems, including in the case of partial observability of the state vector of the object.

2. Model of diagnosed object

In general, non-linear multidimensional diagnosed object (DO) can be described by a model of the form:

\[
\begin{align*}
\dot{x}(t) &= Fx(t) + B(x(t), u(t)) + Gu(t) + Ld(t), \\
y(t) &= Hx(t),
\end{align*}
\]

(1)

where \( x \in R^n \) is state vector, \( n \) is dimensionality of DO, \( y \in R^m \) is output vector, \( u \in R^l \) is input vector, \( p \)-dimensional vector \( d(t) \) describes the errors occurring in the system because of the appearance of faults in it (in the absence of faults all the elements of the vector are zero; in the presence of a fault corresponding element of the vector becomes unknown function of time). \( F \in R^{nxn} \), \( G \in R^{nxl} \), \( H \in R^{mxn} \) are known matrixes. \( B(x(t), u(t)) \) is a vector which determines a non-linear part of the system. In this paper a case where each of the \( d \) elements of vector \( d(t) \) included only in one of the equations of (1) is considered, which means that there is only one nonzero element in each of the columns of matrix \( L \in R^{nxp} \).

The task of detecting faults and determining their values are invited to decide on the basis of logic-dynamic approach (LDA) [1], which allows the construction of diagnostic observers using only linear methods. After synthesis of the diagnostic observers, the special feedback must be introduced in them to ensure stability and to determine the value of the faults occurring in the system.

The developed method provides a set of nonlinear diagnostic observers, each of which is sensitive to one of the faults and invariant to the others. The output signals of observers are the values of the corresponding faults.

As a result of the well-known procedure of synthesis of diagnostic observers based on the LDA [1] \( k \)-dimensional observer sensitive to one of the faults can be built in the following form:

\[
\begin{align*}
\dot{x}^*(t) &= F^*x^*(t) + B^*(x^*(t), u(t)) + G^*u(t) + Jy(t) \\
y^*(t) &= H^*x^*(t)
\end{align*}
\]

(2)

where \( x^* \) is state vector of observer, \( y^* \) is output signal of observer, \( F^* \in R^{kxk} \), \( G^* \in R^{kxl} \), \( H^* \in R^{mxn} \) are matrixes to be determined [1]. On the basis of the outputs of DO and observer following residual is generated:

\[
r(t) = Cy(t) - y^*(t)
\]

(3)
where \( C \) is \( m \)-dimensional vector.

The state vectors of DO and observer are associated by the matrix \( \Phi \in \mathbb{R}^{k \times n} \) [1], and, in the absence of a mismatch between the DO and the observer (if \( r = 0 \)), satisfy the following equation:

\[
x^* = \Phi x
\]  

(4)

In case of any fault the residual (3) becomes different from zero, and the equation (4) is no longer fulfilled.

To solve the problem of identification of faults, consider how residual will change in the event of faults. After differentiating the expression (3) taking into account (1) and (2) it is can be obtained:

\[
\dot{r} = CH(Fx + Gu + B(x, u) + Ld) - H^* (F^* x^* + G^* u + B^* (x^*, u) + Jy),
\]

\[
\dot{r} = CHFx + CHGu + CHB(x, u) + CHLd - H^* F^* x^* - H^* G^* u - H^* B^* (x^*, u) - H^* Jy.
\]

(5)

In view of this, as well as the known relations [1] \( G^* = \Phi G, CH = H^* \Phi, \Phi F = F^* \Phi + JH \), it can be obtained:

\[
\dot{r} = H^* (F^* x^* - H^* F^* x^* - H^* JHx + H^* \Phi B(x, u) - H^* B^* (x^*, u) + H^* \Phi Gu - H^* G^* u + H^* \Phi Ld)
\]

\[
\dot{r} = H^* (F^* (\Phi x - x^*)) + \Phi B(x, u) - B^* (x^*, u) + \Phi Ld)
\]

Denote the value of \( \Phi x - x^* \) as a vector of mismatch of states of DO and the observer:

\[
e = \Phi x - x^*
\]  

(5)

Considering introduced vector, it can be obtained:

\[
\dot{r} = H^* (F^* e + \Phi B(x, u) - B^* (x^*, u) + \Phi Ld)
\]

(6)

Consider the relationship of the vector of mismatch \( e \) with the residual \( r \). In view of (3) it can be obtained:

\[
r = Cy - y^* = CHx - H^* x^* = H^* \Phi x - H^* x^* = H^* e
\]

(7)

From [1] is known that:

\[
F^* = \begin{bmatrix}
0 & 1 & 0 & \ldots & 0 \\
0 & 0 & 1 & \ldots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & 0
\end{bmatrix},
\]

\[
H^* = \begin{bmatrix}
1 & 0 & 0 & \ldots & 0
\end{bmatrix}
\]

(8)

Thus, taking into account the form of vector \( H^* \), the residual \( r \) is the first element of mismatch vector \( e \):

\[
r = e_1
\]

Then, taking into account (6) and (7) it can be obtained:

\[
\dot{e} = F^* e + \Phi B(x(t), u(t)) - B^* (x^*(t), u(t)) + \Phi Ld
\]

(9)

From (9) it follows that the change of the mismatch vector depends on the element \( \Phi B(x(t), u(t)) - B^* (x^*(t), u(t)) \) which characterizes the non-linearity of DO and observer. In the case of incomplete observability of DO, state vector \( x \) and the value of the element \( \Phi B(x(t), u(t)) \) is unknown. It is making difficult identifying of value of faults. In LDA observer constructed in way to compensate the effect of non-linearity in the residual signal and \( \Phi B - B^* = 0 \). However, this condition is fulfilled only when there is no mismatch between the state vectors of DO and observer and \( e = 0 \). To determine the value of fault \( d \) which we are interested, feedback by residual signal formed in such way to provide mismatch elimination even in the case of faults should be introduced.
3. Introduction of feedback

After the introduction of feedback by residual signal in the observer his model assumes the form:

\[
\begin{align*}
\dot{x}^*(t) &= F^* x^*(t) + B^*(x^*(t), u(t)) + G^* u(t) + w(r) + Jy(t) \\
y^*(t) &= H^* x^*(t)
\end{align*}
\]  

(10)

where \( w(r) \in R^k \) is a vector specifying feedback by residual signal.

Taking into account the introduced feedback, change of the mismatch vector will be determined by the equation:

\[
\dot{e} = F^* e + \Phi B(x, u) - B^*(x^*, u) + \Phi L d - w(r)
\]  

(11)

If formed feedback ensures that the equalities (4) and \( B^*(x(t), u(t)) = \Phi B(x^*(t), u(t)) \) are performed, nonlinearity in the process of identification of faults will be compensated:

\[
\dot{e} = F^* e + \Phi L d - w(r)
\]  

(12)

To ensure the sensitivity of observer to the fault \( d_i \) and the invariance of the rest, matrix \( \Phi \) is constructed so that all the columns of matrix \( \Phi L \) except \( i \)th were zero\(^1\). Since each column of the matrix \( L \) may have only one nonzero element, in the matrix \( \Phi L \) will be only one element \( f_k \) not equal to zero. Considering the form of the matrices \( F^* \) and properties of matrices \( \Phi \) and \( L \) equation (12) can be written as:

\[
\begin{align*}
\dot{e}_1 &= e_2 - w_1(e_1) \\
\dot{e}_2 &= e_3 - w_2(e_1) \\
\dot{e}_3 &= e_4 - w_3(e_1) \\
&\vdots \\
\dot{e}_k &= f_k d_i - w_k(e_1).
\end{align*}
\]  

(13)

The system of equations (13) can be represented as a block diagram (Figure 1) describing the behavior of the residual depending on occurring fault. On the diagram value of the fault arising in the DO presented in the form of the input signal, and estimated value of the fault as an output.

![Block diagram of a diagnostic process relative to the mismatch vector e](image)

Fig. 1. Block diagram of a diagnostic process relative to the mismatch vector e

To fulfill the condition \( e \rightarrow 0 \) for a fault of constant size, introducing of integration of the output signal of the open circuit of diagnostic system (Figure 1) can be used:

\[
w_k(e_1) = \int(w_k^*(e_1))dt
\]

In this case, the order of equation (13) increases by 1 and becomes \( k + 1 \). 

The next necessary condition to eliminate mismatch between the DO and the observer is to ensure the stability of the observer. The transition process should be damped in time. It is known that for the stability of the system the real parts of all roots of the characteristic equation must be less than 0.

Writing the system of equations (13) in the form of a differential equation we get:

\[ f_k \frac{d e_k}{dt} = e_k + w_k = e_{k-1} + w_{k-1} + w_k = e_{k-2} + w_{k-2} + w_{k-1} + w_k = e_1^{(k)} + w_1^{(k-1)} + \ldots + w_1^{(1)} + w_k \]

Accepting elements of the vector of feedback, except the k-th, proportional to the residual \( w_i = \frac{T_i}{T_0} e_1 \) (\( i = 1, k - 1 \)) it can be obtained:

\[ f_k d_i = e_1^{(k)} + \frac{T_1}{T_0} e_1^{(k-1)} + \ldots + \frac{T_{k-1}}{T_0} e_1^{(2)} + w_k^* (e_i) + \int (w_k^* (e_i))dt \]

By differentiating it can be obtained:

\[ f_k d_i^{(1)} = e_1^{(k+1)} + \frac{T_1}{T_0} e_1^{(k)} + \ldots + \frac{T_{k-1}}{T_0} e_1^{(2)} + w_k^* (e_i) \]  \hspace{1cm} (14)

As can be seen, in this equation there is no term with the first derivative of the residual. This corresponds to the presence of roots of the characteristic equation with real part above zero. To add a missing term in the equation must be:

\[ w_k^* (e_i) = \frac{T_k}{T_0} e_1^{(i)} + \frac{1}{T_0} e_i. \]  \hspace{1cm} (15)

Then, feedback \( w_k(r) \) takes the form:

\[ w_k (e_i) = \int \left( \frac{T_k}{T_0} e_1^{(i)} + \frac{1}{T_0} e_i \right) dt = \frac{T_k}{T_0} e_1 + \frac{1}{T_0} e_i dt \]  \hspace{1cm} (16)

The equation (14) takes the form:

\[ T_0 f_k d_i^{(i)} = T_0 e_1^{(k+1)} + T_1 e_1^{(k)} + \ldots + T_{k-1} e_1^{(2)} + T_k e_1^{(1)} + e_i. \]  \hspace{1cm} (17)

Thus, after the introduction of this kind of feedback, residual \( e_1 \) will tend to zero, after the completion of the transition process, including in the event of faults. This will ensure the synchronization of state vectors of DO and observer.

### 4. Determination of values of faults

The next step of solving the problem is estimation of value of the desired fault. Since the introduction of the feedback was able to arrange that \( e = 0 \) taking into account (12) it can be written:

\[ 0 = \Phi Ld - w(r), \]

\[ w(r) = \Phi Ld. \]

Thus, given the form of desired matrixes \( \Phi \) and \( L \) estimation of fault value \( d_i^* \) can be found by the following method:

\[ d_i^* = \frac{w_k (e_i)}{f_k}, \]  \hspace{1cm} (18)

where \( w_k (e_i) \) is element of the vector of feedback, \( f_k \) is element of the \( i \)th column of the matrix \( \Phi L \). In view of (15) it can be obtained:
\[
d_i^* = \frac{1}{f_k} T_0 \left( e_1 + \frac{1}{T_0} \int e_i dt \right)
\]

Given the fact that \( e_1 = 0 \), \( d_i \) fault can be found by integrating the residual \( e_i \):

\[
d_i^* = \frac{1}{f_k T_0} \int e_i dt.
\]

Thus the output of the system of identification of faults after the of transient processes will be sought value \( d_i \). The required system performance can be achieved by selection of \( T_0, T_k \) coefficients.

5. Example

Consider nonlinear DO of the third order, described by the following matrixes:

\[
F = \begin{bmatrix} 0 & 0.01 & 0 \\ 0 & -1000 & 200 \\ 0 & -5 & -100 \end{bmatrix}, \quad G = \begin{bmatrix} 0 \\ 0 \\ 250 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 0 & 1 \end{bmatrix}, \quad L = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 5 \sin(x_2) \end{bmatrix}
\]

In this example, the dimension of the output of the system is less than the dimension of the state vector. Thus, only the value of \( x_1 \) and \( x_2 \) are observable and \( x_2 \) is not observable. Suppose, it is required to build the observer to determine the size of the fault \( d_i \), acting on 2nd equation of the system. The observer for the fault \( d_i \), built with the help of LDA will be described by the following matrix:

\[
C = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad J = \begin{bmatrix} -1000 & 0 \\ 0 & 2 \end{bmatrix}, \quad \Phi = \begin{bmatrix} 1 & 0 & 0 \\ 1000 & 0.01 & 0 \end{bmatrix}, \quad G^* = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad B^* = \begin{bmatrix} 0 \\ 0.05 \sin(100 x_2^* - 10000 x_1^*) \end{bmatrix}
\]

Model (13) for this case will be:

\[
\begin{align*}
\dot{e}_1 &= e_2 - w_1, \\
\dot{e}_2 &= f_2 d_i - w_2,
\end{align*}
\]

where \( f_2 = 0.01 \).

The equation(17) takes the form:

\[
f_k d_i^{(1)} = e_1^{(3)} + T_1 e_1^{(2)} + T_2 e_1^{(1)} + e_1.
\]

The conducted research has shown at the synthesis of such observer of the third order is desirable to choose,

\[
T_0 = \left( \frac{1}{9} T_s \right)^3, \quad T_1 = 3 \left( \frac{1}{9} T_s \right)^2, \quad T_2 = 3 \frac{1}{9} T_s \quad \text{where} \quad T_s \quad \text{is a time at which output signal reaches 5% closeness of fault value.}
\]

If \( T_s = 0.1 \) s. we obtain:

\[
T_0 = 1.372 \cdot 10^{-6}, \quad T_1 = 3.7 \cdot 10^{-4}, \quad T_2 = 0.033,
\]

\[
w_1 = \frac{T_1}{T_0} e_1 = 270 e_1, \quad w_2 = \frac{T_1}{T_0} e_1 + \int \frac{1}{T_0} e_1 dt = 24300 e_1 + 729000 \int e_1 dt
\]

To verify the functionality and effectiveness of the proposed method, the modeling of the synthesized observer was carried out. Faults were simulated by introducing a \( d_1 = 10 \) (Figure 2) and \( d_1 = 10 \sin(5t) \) (Figure 3) from \( t=5 \) s., to \( t=10 \) s. and \( d_2 = 5 \), from \( t=3 \) s.
As can be seen, the system accurately determines the presence or absence of a fault $d_1$ and its value. In addition, as required, fault $d_2$ does not affect the determination of $d_1$. Thus, the results of mathematical modeling is fully confirmed the efficiency and high performance of the proposed method of synthesis of diagnostic observers for identification of faults in nonlinear dynamic systems.

6. Conclusion

In this paper, we considered new method of detection, localization and identification of values of faults of the nonlinear dynamic systems. This method consists of applying of logic-dynamic approach for synthesis of diagnostic observers, guaranteeing the independence of the detection and localization of possible faults and introducing of special feedback for diagnostic observers, allowing identifying values of faults. The advantage of this method is the simplicity of implementation and accuracy of the identification of faults. Efficiency of the proposed method of synthesis of diagnostic observers for identification of faults in nonlinear dynamic systems was confirmed by the results of mathematical modeling. The subject of further research will be application of the proposed method for synthesis of the fault accommodation and failsafe control systems for such objects as industrial manipulators and underwater vehicles.
